# Abstract

This thesis is a series of publications that introduce novel methods for human neural rendering using limited information, focusing on Neural Radiance Fields (NeRFs) and 3D Gaussian Splatting (3DGS). It explores how these models construct 3D representations from 2D images and demonstrates ways to condition these representations for generating high-quality human renderings. We propose techniques that use simple, interpretable inputs derived from sparse training data and extends these methods to perform effectively in few-shot learning scenarios.

We begin by examining the field of neural radiance fields, addressing limitations in existing approaches and presenting contributions to controllable radiance fields. By incorporating partial and sparse data during training, it leverages the smoothness of neural networks to produce controllable, high-quality human images.

To tackle the reliance on extensive, high-quality data annotations from multi-view videos, we introduce a new method for training neural radiance fields in few-shot, multi-view settings. This approach learns internal deformation templates, which blend smoothly during inference, significantly improving image quality compared to existing baselines and enabling effective human rendering from limited input images.

The work also addresses the need for adaptable computational efficiency during inference. It proposes a fine-to-coarse learning strategy for 3D Gaussian Splatting, which upscales a latent 2D grid that stores Gaussian representations. This strategy achieves competitive results while allowing deployment on various computational devices with minimal quality loss.

In addition, we develop a novel model for controlling radiance fields through environmental lighting. By incorporating precomputed radiance transfer, this model enables physically plausible scene relighting and provides users with intuitive control over lighting in reconstructed scenes.

This research advances the state of the art in controllable neural radiance fields and expands their application to few-shot learning scenarios. These innovations enhance the possibilities for human rendering from limited information and open new directions for future research in the field.

# Introduction

With the advent of deep learning, research have been exploring varying ways to apply it to computer graphics. One of the most recent and promising approaches is neural rendering. Neural rendering is a field that combines deep learning and computer graphics to generate realistic images of 3D scenes. The neural radiance field (NeRF) is a popular neural rendering technique that represents a 3D scene as a continuous function that maps 3D coordinates to radiance values. NeRF has shown impressive results in generating photorealistic images of 3D scenes. However, NeRF has limitations in terms of memory and computational requirements, which makes it difficult to scale to large scenes.

To alleviate the problem, Kerbl *et al.* [14] proposed a new technique—3D Gaussian Splatting (3DGS). 3DGS is a neural rendering technique that represents a 3D scene as a set of 3D Gaussian that are splatted to an image space using algorithm proposed by Zwicker *et al.* [36]. In contrast to NeRF, 3DGS is more memory efficient and can be used to render large scenes. It can also render scenes with millions of points in real-time on a single GPU.

In this thesis, we focus on those two milestone techniques in neural rendering and address their fundamental problem—lack of controllability.

## 1.1 Motivation and challenges

NeRF and 3DGS are both impressive techniques that can generate realistic images. However, a single scene representation needs to be trained on a high-end GPU for hours or even days just to render a novel view at the inference time. However, any type of controllability is difficult to achieve with those models. That includes changing the lighting conditions, subject's attributes or even the scene itself. We see imbuing those models with controllability as a an important step towards making them more useful in practice. Our proposed models are designed to address this issue.

One may ask why the controllability is a feat sought after to be researched. We see the inspiration in how human artists work. Imagine an artist working on 3D game where they

need an asset, like a 3D mesh, to be created. Such a mesh takes much effort since it includes modeling, creating a UV map which can then be textured. After the process is finish, the artist's supervisor may task him to change the model to some extent which requires the artist to redo all the effort again. Such a process is not limited to 3D assets as meshes and could be applied to 3DGS or NeRF. However, 3DGS and NeRFs are volumetric in nature. Our exploited and well-established practices no longer apply to them since volumetric representations do not have the underlying surface representation. For that reason, we see a couple of avenues which we explore in this thesis.

Firstly, Park *et al.* [22] proposed NeRFies, a model that creates a volumetric representation of a person from a self-captured sequence with a phone camera. Since the inception of NeRFs [18], it was among the first works the achieved such a high quality of reconstructions from a casual videos. In its primal form, NeRFies were unable to control the avatar in any other way than by a linear interpolation of latent embeddings that embedded the video's time dimension. The follow-up work, HyperNeRF [21] handles this issue by projecting the learnable embeddings with $D$ onto a lower-dimensional space $\mathbb{R}^d$ where $d \ll D$. After the assumption that the $d=2$ is enough to explain the sequence variability, that projected embedding becomes a 2-dimensional space that can be traversed in an interpretable way. However, that space is not intuitive since the projection is a non-linear operation and one cannot predict how values affect the results. To mitigate that issue, we propose to leverage smoothness of Multilayer Perceptrons (MLPs) [22, 29] to constrain the projection via sparse supervision. We realize our approach as a weakly-supervised MLP that out of many images from the sequence (we assume at least 100 frames in our work) only a few are provided with a coarse annotation. Such annotations denote what values a chosen attribute takes and where its effect spans in the image space. We show that our method, which we dubbed CoNeRF [12] and published at the CVPR 2022 conference, imbues NeRFs with a flexible editability feature without the lose of the rendering quality.

Secondly, approaches such as CoNeRF [12], EditNeRF [16] or FigNeRF [31] focus solely on static elements of the scene, hence their controllability is limited to changing colors or textures in general. HyperNeRF [21] arises as a potential solution due to its ability to model object deformations. However, our initial experiments showed that those changes cannot handle motions that affect a subject globally, *e.g.*, jumping jacks performed by a person. To solve the issue, Fang *et al.* [3] proposes to model the deformation via a multi-scale voxel structure which works well in the synthetic setting, such as the one proposed by Pumarola *et al.* [24].

There exists a plethora of works that approach the problem from the another angle—instead of modeling the motion purely from data, they use a template model in the form of a 3D mesh to canonicalize deformed points [35]. Such methods rely on the accuracy of the *registration*, *i.e.*, fitting the template mesh to subject. Since the registration methods [4, 34] are imperfect estimators, they inherently contain registration errors. Those deviations are exacerbated by learnable radiance field models which assume a perfectly calibrated scene. The authors of those approaches usually mitigate the issue with additional latent space [7, 12, 17] that requires

thousands of video frames to learn an avatar of high-fidelity that reacts correctly to deformations such as wrinkles on the forehead. At the same time, performing the registration on the large scale is costly [1]. In this thesis, we seek a remedy for those obstacles. We propose a method that is data-efficient, easy to improve with a minimal user input and can model realistic deformation dependent changes in the subject. Inspired by classical methods in character texturing [20] and motion modeling [15], we propose BlendFields [13], an *homage* to traditional blendshapes [15]. We build on VolTeMorph's [6] approach to point canonicalization to provide a data-efficient way to control the character. We further introduce a physically-based mixture of predefined, learned from data wrinkle templates that represent expression-dependent skin deformations. Our proposed was acknowledged by the reviewers and was accepted to the CVPR 2023 conference.

Thirdly, having the texture and coarse mesh-based controllability, we strive for control scene settings directly. The inverse rendering of 3D scenes is an ill-posed problem where many different lighting settings may explain the same light effects [23]. To facilitate solving the problem, many approaches use datasets of single object's images captured under different lighting conditions [2, 27, 32]. These approaches cannot decouple albedo from the lighting effects [2, 32] or need additional neural networks to predict correct shadows [27] which limits methods' practicality. We propose to use recently proposed 2D Gaussian Splatting [9] which exhibit remarkable quality of the surface reconstruction. Together with our precomputed radiance transfer from classical computer graphics approaches [25, 28], our LumiGauss achieves state-of-the-art reconstruction quality with the ability to render novel lighting conditions with high fidelity. Our work received positive reviews for the WACV 2025 conference.

Finally, volumetric representation are computationally intensive to render, compared to the traditional mesh representation. For NeRFs [18], it takes seven days on V100 NVidia GPU to train for single scene, and more than 60 seconds to render a single image—way beyond any practical applications. Although many approaches have been proposed to speed up the rendering process [5, 8, 19, 26, 33], they usually make a trade-off between memory requirements, quality, and rendering speed. 3D Gaussian Splatting [14] (3DGS) rose as an alternative to NeRF, offering both high-quality rendering at interactive frame rates. However, those frame rates could be achieved with the most advanced GPU units available at that time. As we see the potential in 3DGS to be a viable canonical representation for 3D data, akin to 3D meshes, a need for its adaptability to different computational resources exists. Meshes can be adapted easily with levels of detail (LoD) approaches that remove detail from meshes that do not affect the general object's perception if necessary.

## 1.2   Research objectives

In this thesis, we explore different avenues of radiance field controllability. With this goal in mind, we aim at answering the following research questions:

(**RQ 1**) Can we imbue a Neural Radiance Field (NeRF) with a controllability by providing sparse annotations to the training dataset? How many annotations suffice to learn smooth interpolation capabilities between controlled values?

(**RQ 2**) Are extreme facial expressions known from the literature sufficient to learn expression-dependent details that extrapolate to expressions unseen at the training time?

(**RQ 3**) Is it possible to learn an underlying radiance transfer function of a scene from images taken in "in-the-wild" setting? Can such a transfer function generalize to unknown environment maps?

(**RQ 4**) How to learn a single 3D Gaussian Splatting (3DGS) representation that can be adapted to different computational regimes at inference time in a feed-forward mode?

Each of these questions is a representative of possible among many others controllability directions for radiance fields. In case of this thesis, we present summarize our methods as controls of: texture [12, 13], shape [13], lightning [10] and use of resources [11]. To answer (**RQ 1**), we describe our CoNeRF [12]. It is one of the pioneering works that uses sparsely annotated frames to continuously control the subject in a post-hoc manner. We leverage the fact that MLP used in NeRFs are smooth functions biased towards low frequency signals [29]. For that reason, NeRF can learn to interpolate smoothly the annotation signal between frames of high similarity. We show that this assumption is sufficient to obtain both novel view synthesis and novel attribute synthesis with a single model.

We further move towards answering (**RQ 2**). We introduce BlendFields [13], achieving two primary goals: ability to generalize unknown expressions via a predefined face mesh template, and a mixture model of training expressions that can produce spatially coherent, expression-dependent wrinkles on the face from as few as three expressions. In our work, we build on VolTeMorph [6] to achieve to former, and focus on the latter contribution. Inspired by texture maps in classical computer graphics pipelines [20], we define a set of learnable radiance fields, each being overfit to a particular extreme expression from the training set. We define an extreme expression as one of the possible expressions involving the most facial muscles. Building on VolTeMorph [6] allows us to use an underlying tetrahedral mesh to compute physical quantities such as the volume change of tetrahedra under a given expression. We use those quantities to linearly interpolate between the pretrained radiance fields. We mix the tetrahedra independently which makes rendering novel expressions possible. For example, BlendFields can render one of the eyebrows raised while maintaining the other in a natural position, which is a difficult expression to make for majority of people.

Our LumiGauss [10] answers (**RQ 3**). In contrary to common approaches [27], we posit that the radiance transfer function known among computer graphics researchers [25] can be learned from unconstrained photo collection under varying lighting conditions. To this end, we use 2DGS [9] which gives us a smooth shape representation, difficult to achieve when

using 3DGS [14]. With the use of contributed priors, we induce learning Gaussian's Spherical Harmonics such that they correctly react to changing environment maps. Not only our approach is fast to train, but renders realistic scenes and object's shadows even under novel lighting conditions.

All the contributions so far are affected by a specific disadvantage—a single model needs to be trained from scratch and it can be deployed only on high-end hardware. We then ask if we can train a single model that is adaptable at inference time to different hardware regimes (**RQ 4**). We propose CLoG [11] as a potential remedy. Our approach uses the fact that one can constrain the number of Gaussians in 3DGS [14] to a specific number, such that it can be formed as a 2D grid by simple reshape operation. With a specific training coarse-to-fine training protocol we contributed, the model learns a representation that converges to a high-quality volumetric structure. In the second training stage, we leverage the fact that Gaussians's can be spatially sorted in such a manner that their descriptors are placed next to each other if they are similar. That forms a low-frequency image which can be modulated with an off-the-shelf continuous upsampling architecture [30]. The architecture outputs a new grid of the given resolution. We show in our work that such an approach achieves remarkable results and can output any number of Gaussians at inference time with high quality.

## 1.3 Contributions

Building on those questions, we structure this thesis in several chapters corresponding to the answers. An answer is in a form of a scientific article where we introduce the following:

- A novel approach for controlling trained radiance fields with the use of sparsely annotated images from a casually captured data.

- A new model capable of blending trained radiance fields from multi-view frames in an interpretable way and extrapolating to novel human expressions for the trained subject.

- The first use of Gaussian Splatting methods that learns a coherent shape representation of a subject and an ability to distill the varying lighting conditions in the data to a radiance transfer function.

- A novel paradigm for learning Gaussian Splatting models as 2D grids to achieve flexibility to adapt the model to different computational regimes at inference time.
